An Efficient Numerical Integration Algorithm for Cellular Neural Network Based Hole-Filler Template Design

V. Murugesh, Krishnan Batri

Abstract: This paper presents, a design method for the template of the hole-filler used to improve the performance of the character recognition using Numerical integration algorithms. This is done by analyzing the features of the hole-filler template and the dynamic process of CNN and by using popular numerical algorithms to obtain a set of inequalities satisfying its output characteristics as well as the parameter range of the hole-filler template. Some simulation results and comparisons are also presented.

Keywords: Cellular Neural Networks; Euler Algorithm; RK-Gill Algorithm; RK-Butcher Algorithm; Ordinary differential equations, Hole-filler.

1 Introduction

Cellular Neural Networks (CNNs) are analog, time-continuous, nonlinear dynamical systems and formally belong to the class of recurrent neural networks. Since their introduction in 1988 (by Chua and Yang [1, 2], it has been the subject of intense research. Initial applications include image processing, signal processing, pattern recognition and solving partial differential equations, etc.

Runge-Kutta (RK) methods have become very popular, both as a computational technique as well as a subject of research, which are discussed by Butcher [3, 4]. This method was derived by Runge around the year 1894 and extended by Kutta a few years later. They developed algorithms to solve differential equations efficiently and these are the equivalent of approximating the exact solutions by matching ‘n’ terms of the Taylor series expansion.

Butcher [3] derived the best RK pair along with an error estimate and by all statistical measures it appeared as the RK-Butcher algorithm. This RK-Butcher algorithm is nominally considered as sixth order, since it requires six function evaluations, but in actual practice the “working order” is close to five (fifth order).

In this paper, we describe the dynamic behavior of CNN in section 2, Hole-filler template design ideas in Section 3, Numerical integration algorithms and its description is shown in Section 4, and simulation results in Section 5.

2 Dynamic Analysis of CNN

The dynamic equation of cell C(i, j) in an M x N cellular neural network is given by Chua and Yang [1, 2].

\[
\frac{dx_{ij}(t)}{dt} = -\frac{1}{R_x} x_{ij}(t) + \sum_{C(k,l) \in N(i,j)} A(i,j;k,l)y_{kl}(t) + \sum_{C(k,l) \in N(i,j)} B(i,j;k,l)u_{kl} + I
\]

\[
y_{ij}(t) = \left[ |x_{ij}(t) + 1| - |x_{ij}(t) - 1| \right], 1 \leq i \leq M, 1 \leq j \leq n
\]
where \(x_{ij}, y_{ij}\) and \(u_{ij}\) are the state voltage, output voltage and input voltage respectively and they are functions of time \(t\). \(R_x\) is a linear resistance, \(C\) is a linear capacitor, and \(A(i, j; k, l)\) and \(B(i, j; k, l)\) are the transconductances of the output and input voltages of \(C(k, l)\) with respect to \(C(i, j)\) called the cloning templates of CNN. \(N_r(i, j)\) denotes the \(r^{th}\) neighbor of \(C(i, j)\) and \(I\) is an independent current source. From equation (2) one can see that the output voltage is nonlinear. We can rewrite the cell equation (1) as follows:

\[
C \frac{dx_{ij}(t)}{dt} = -f[x_{ij}(t)] + g(t)
\]  

(3)

Where

\[
f[x_{ij}(t)] = \frac{1}{R_x} x_{ij}(t)
\]  

(4)

\[
g(t) = \sum_{C(k,l) \in N_r(i,j)} A(i, j; k, l) Y_{kl}(t) + \sum_{C(k,l)} B(i, j; k, l) U_{kl} + I
\]  

(5)

### 3 Hole-filler Template Design

The Hole-Filler is a cellular neural network discussed by Yin et al [9], which fills up all the holes and remains unaltered outside the holes in a bipolar image. Let \(R_x = 1\), \(C = 1\) and let +1 stand for the black pixel and -1 for the white one. We shall discuss the images having holes enclosed by the black pixels, when the bipolar image is input with \(U = \{u_{ij}\}\) into CNN. The initial state values are set as \(X_{ij}(0) = 1\).

From the equation (2) the output values are \(Y_{ij}(0) = 1\), \(1 \leq i \leq M\), \(1 \leq j \leq N\).

Suppose that the template \(A\) and \(B\) and the independent current source \(I\) are given as

\[
A = \begin{bmatrix} 0 & a & 0 \\ a & b & a \\ 0 & a & 0 \end{bmatrix}, \quad a > 0, \quad b > 0, \quad B = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad I = -1
\]

(6)

Where the template parameters \(a\) and \(b\) are to be determined. In order to make the outer edge cells become the inner ones, normally auxiliary cells are added along the outer boundary of the image, and their state values are set to zeros by circuit realization, resulting in the zero output values. The state equation (1) can be rewritten as

\[
\frac{dx_{ij}(t)}{dt} = -x_{ij}(t) + \sum_{C(k,l) \in N_r(i,j)} A(i, j; k, l) Y_{ij}(t) + 4u_{ij}(t) - I
\]  

(7)

For the cell \(C(i, j)\), we call the cells \(C(i+1, j)\), \(C(i-1, j)\), \(C(i, j+1)\) and \(C(i, j-1)\) to be the non-diagonal cells. Here, several cases are to be considered.
**Case 1:** The input value $u_{ij} = +1$ for cell $C(i, j)$, signaling the black pixel. Because the initial state value of the cell $C(i, j)$ has been set to 1, $x_{ij}(0) = 1$, and from equation (2) its initial output value is also $y_{ij}(0) = 1$. According to the hole-filler demands, its eventual output should be $y_{ij}(\infty) = 1$. To obtain this result we set

$$\frac{dx_{ij}(t)}{dt} \geq 0$$

Substituting this input $u_{ij} = 1$ and equation (6) into equation (7), we obtain

$$\frac{dx_{ij}(t)}{dt} = -x_{ij}(t) + a \left[ y_{(i-1)j}(t) + y_{(i+1)j}(t) + y_{i(j-1)}(t) + y_{i(j+1)}(t) \right] + by_{ij}(t) + 3 \tag{9}$$

Combining equations (8) and (9) and considering the minimum value of $x_{ij}(t) = 1$ this case yields

$$a \left[ y_{(i-1)j}(t) + y_{(i+1)j}(t) + y_{i(j-1)}(t) + y_{i(j+1)}(t) \right] + by_{ij}(t) + 2 \geq 0 \tag{10}$$

To facilitate our discussion, two sub cases are distinguished.

**Sub Case 1:** The cell $C(i, j)$ is inside the holes. Since $x_{ij}(0) = 1$, from equation (2) its initial output value $y_{ij}(0) = 1$. Considering equations (8) and (2), $y_{ij}(t) \geq 1$. According to the hole-filler demands, its initial output of non-diagonal black pixels should not be changed inside the holes. The weights of $a$ and $b$ are equal to +4 and +1, respectively.

Since $A(i, j; k, l) > \frac{1}{16}$ the parameter $b$ is found to be $b > 1$, or

$$4a + b + 2 \geq 0, \quad b > 1 \tag{11a}$$

**Sub Case 2:** The cell $C(i, j)$ is outside the holes. To satisfy equation (10), we need to check only the minimum value on the left-hand side of equation (10). This is true when there are four non-diagonal white pixels around the cell $C(i, j)$, where the weight of $a$ in equation (10) is -4. Since $y_{ij}(t) \geq 1$, the weight of $b$ is equal to 1. Combining this with $b > 1$ gives

$$-4a + b + 2 \geq 0, \quad b > 1 \tag{11b}$$

**Case 2:** The input value of cell $C(i, j)$ is $u_{ij} = 1$, signaling the white pixel. Substituting this input value in equation (7) gives

$$\frac{dx_{ij}(t)}{dt} = -x_{ij}(t) + a \left[ y_{(i-1)j}(t) + y_{(i+1)j}(t) + y_{i(j-1)}(t) + y_{i(j+1)}(t) \right] + by_{ij}(t) - 5 \tag{12}$$

**Sub Case 1:** The cell $C(i, j)$ is inside the holes. Since $x_{ij}(0) = 1$, from equation (2) its initial output value is $y_{ij}(0) = 1$. According to the hole-filler demands, the holes should be filled by the black pixels, whereas its initial black pixels remain unaltered:

$$\frac{dx_{ij}(t)}{dt} \geq 0 \tag{13}$$

Combining equations (12) and (13) and considering $x_{ij}(t) \geq 1$ yields

$$a \left[ y_{(i-1)j}(t) + y_{(i+1)j}(t) + y_{i(j-1)}(t) + y_{i(j+1)}(t) \right] + by_{ij}(t) - 6 \geq 0 \tag{14}$$

where we use the minimum value of $x_{ij}(t)$ in equation (12). Since the cell is inside the holes, its initial output of non-diagonal black pixels remain unchanged. The weight of $a$ and $b$ are equal to +4 and +1, respectively. Combining this with $b > 1$ gives

$$4a + b - 6 \geq 0, \quad b > 1 \tag{15}$$
Sub Case 2: The cell C(i, j) is outside the holes. Since \( x_{ij}(0) = 1 \), from equation (2) its initial output value is \( y_{ij}(0) = 1 \). According to the hole-filler demands, the final output of this cell should be white, and in this case \( y_{ij}(\infty) \leq -1 \).

\[
\frac{dx_{ij}(t)}{dt} < 0
\]  

(16)

Combining equations (12) and (16) and considering \( x_{ij}(t) \leq 1 \). we get

\[a[y_{(i-1)j}(t) + y_{(i+1)j}(t) + y_{(i-1)(j-1)}(t) + y_{(i+1)(j+1)}(t)] + by_{ij}(t) - 6 < 0 \]

(17)

where we use the maximum value of \( x_{ij}(t) \) in equation (12).

Initially \( y_{ij}(0) = 1 \). How can the output of cell \( C(i, j) \) be changed to -1? Where does this change begin? First we consider the situation where the change begins from the inside of the bipolar image. If the maximum value on the left-hand side in equation (17) is less than zero, equation (17) holds. Inside the image and outside the holes, the maximum weights of a and b are +4 and +1, respectively. This case was described by equation (15). In fact, the change of the output of the cell \( C(i, j) \) is like a wave propagating from the edges to the inside of the image and it is verified from the simulated result. Therefore, we should first consider the edge cell \( C(i, j), i = 1 \) or \( M, j = 1 \) or \( N \). For this the maximum weight of a in equation (17) is +3, which is also the maximum weight of a outside the holes. The maximum weight of b is +1, occurring at the initial time:

\[3a + b - 6 < 0, \quad b > 1 \]

(18)

Combining Cases 1 and 2, we obtain

\[
\begin{align*}
3a + b - 6 &< 0, \\
4a + b - 6 &\geq 0, \\
-4a + b + 2 &\geq 0.
\end{align*}
\]

(19)

4 Numerical Integration Algorithms

The CNN dynamics on a digital architecture requires discretization in time and suitable numerical integration algorithms. Three of the most widely used Numerical Integration Algorithms are used in Raster CNN Simulation described here. They are the Euler’s Algorithm, RK-Gill Algorithm discussed by Oliveria [8] and the RK-Butcher Algorithm discussed by Badder [5, 6] and Murugesh and Murugesan [10, 11, 12].

4.1 Euler Algorithm

Euler’s method is the simplest of all algorithms for solving ODEs. It is explicit formula which uses the Taylor-series expansion to calculate the approximation.

\[
x_{ij}((n+1)\tau) = x_{ij}(n\tau) + \tau f'(x(n\tau))
\]

(20)

4.2 RK-Gill Algorithm

The RK-Gill algorithm discussed by Oliveria [8] is an explicit method requiring the computation of four derivatives per time step. The increase of the state variable \( x^{ij} \) is stored in the constant \( k_{ij}^{(k)} \). This
result is used in the next iteration for evaluating $k^{ij}_2$. The same must be done for $k^{ij}_3$ and $k^{ij}_4$.

$$
k^{ij}_1 = f'(x_{ij}(\tau \pi))
$$

$$
k^{ij}_2 = f'(x_{ij}(\tau \pi) + \frac{1}{2} k^{ij}_1)
$$

$$
k^{ij}_3 = f'(x_{ij}(\tau \pi) + \left(\frac{1}{\sqrt{2}} - \frac{1}{2}\right) k^{ij}_1 + \left(1 - \frac{1}{\sqrt{2}}\right) k^{ij}_2)
$$

$$
k^{ij}_4 = f'(x_{ij}(\tau \pi) - \frac{1}{\sqrt{2}} k^{ij}_2 + \left(1 + \frac{1}{\sqrt{2}}\right) k^{ij}_3)
$$

The final integration is a weighted sum of the four calculated derivatives:

$$x_{ij}((n+1) \tau) = x_{ij} + \frac{1}{6} \left[ k^{ij}_1 + \left(2 - \sqrt{2}\right) k^{ij}_2 + \left(2 + \sqrt{2}\right) k^{ij}_3 + k^{ij}_4 \right]
$$

### 4.3 RK-Butcher Algorithm

The RK-Butcher algorithm discussed by Badder [5, 6] and Murugesh and Murugesan [10, 11, 12], is an explicit method. It starts with a simple Euler step. The increase of the state variable $x_{ij}$ is stored in the constant $k^{ij}_1$. This result is used in the next iteration for evaluating $k^{ij}_2$. The same must be done for $k^{ij}_3$, $k^{ij}_4$, $k^{ij}_5$ and $k^{ij}_6$.

$$
k^{ij}_1 = \tau f'(x_{ij}(\pi \tau))
$$

$$
k^{ij}_2 = \tau f'(x_{ij}(\pi \tau) + \frac{1}{4} k^{ij}_1)
$$

$$
k^{ij}_3 = \tau f'(x_{ij}(\pi \tau) + \frac{1}{8} k^{ij}_1 + \frac{1}{8} k^{ij}_2)
$$

$$
k^{ij}_4 = \tau f'(x_{ij}(\pi \tau) - \frac{1}{2} k^{ij}_2 + k^{ij}_3)
$$

$$
k^{ij}_5 = \tau f'(x_{ij}(\pi \tau) + \frac{3}{16} k^{ij}_1 + \frac{9}{16} k^{ij}_4)
$$

$$
k^{ij}_6 = \Delta t f'(x_{ij}(\pi \tau) - \frac{3}{7} k^{ij}_1 + \frac{2}{7} k^{ij}_2 + \frac{12}{7} k^{ij}_3 - \frac{12}{7} k^{ij}_4 + \frac{8}{7} k^{ij}_5)
$$

The final integration is a weighted sum of the five calculated derivatives:

$$x_{ij}((n+1) \tau) = \frac{1}{90} \left( 7k^{ij}_1 + 32k^{ij}_3 + 12k^{ij}_4 + 32k^{ij}_5 + 7k^{ij}_6 \right)
$$

### 5 Simulated Results

This Hole-filler template has been simulated using Pentium IV Machine with 3.0 Ghz speed using different Numerical integration algorithms. The Settling time $T_s$ and integration time $T_i$ is obtained with various step sizes is to be displayed below in the Table-1. The settling time $T_s$ describes the time from start of integration until the last cell leaves the interval $[-1.0, 1.0]$ which is based on certain limit (e.g., $|\frac{dx}{dt}| < 0.01$). The simulation shows the desired output for every cell. We use +1 and -1 to indicate the black and white pixels, respectively.

Table 1: Simulated Results of Hole-Filler Template Design

Example
The templates A, B and I are given as follows:

\[
A = \begin{bmatrix}
0 & 1.0 & 0 \\
1.0 & 3.0 & 1.0 \\
0 & 1.0 & 0.0
\end{bmatrix}, \quad B = \begin{bmatrix}
0 & 0 & 0 \\
0 & 4 & 0 \\
0 & 0 & 0
\end{bmatrix}, \quad I = -1.0
\]

Using the simulation program developed in C++, the input image is shown in Figure-2(a) and the output image in Figure-2(b). The obtained result is represented in Table-1. From the table-1, we find that RK-Butcher algorithm yields less settling time and integration time compared to Euler and RK-Gill algorithms.

6 Conclusion

It is shown that the cellular neural network based hole-filler template could be designed from its dynamic behavior using different numerical algorithms, and also the template for other cellular neural network can similarly be designed. The hole is filled and the outside image remains the same. The templates of the cellular neural network are not unique and this is important in its implementation.
